Flow problem: basic definitions

- Basic setup: we are given a directed graph G = (V, E), which includes a special node s called the *source* and a node t called the *sink*. Each edge e is associated with a capacity c_e ≥ 0.
- This is called a *flow network*.

Flow problem: basic definitions

- Basic setup: we are given a directed graph G = (V, E), which includes a special node s called the *source* and a node t called the *sink*. Each edge e is associated with a capacity c_e ≥ 0.
- This is called a *flow network*.

Definition

- A flow is a function $f: E \to \mathbb{R}^+$ satisfying:
 - capacity conditions $\forall e \in E, 0 \leq f(e) \leq c_e$.

 ${f O}$ conservation conditions $\forall u \in V \setminus \{s, t\},$

$$\sum_{e \text{ into } v} f(e) = \sum_{e \text{ out of } v} f(e).$$

The value of a flow f is $|f| \coloneqq \sum_{e \text{ out of } s} f(e)$.

Definition

- A flow is a function $f: E \to \mathbb{R}^+$ satisfying:
 - capacity conditions $\forall e \in E, 0 \leq f(e) \leq c_e$.

2 conservation conditions $\forall u \in V \setminus \{s, t\}$,

$$\sum_{e \text{ into } v} f(e) = \sum_{e \text{ out of } v} f(e).$$

The value of a flow f is $|f| \coloneqq \sum_{e \text{ out of } s} f(e)$.

The maximum flow problem: given a flow network, compute a flow with maximum value.

Given a flow f in a flow network G, the *residual graph* G_f is defined as follows.

- G_f has the same set of nodes as G (including s and t);
- for each e = (u, v) of G on which $f(e) < c_e$, e is in G_f and has capacity $c_e f(e)$; (such an edge is called a *forward edge* in G_f)
- for each e = (u, v) of G on which f(e) > 0, (v, u) is in G_f , and has capacity f(e). (such an edge is called a *backward edge* in G_f)

Given a flow f in a flow network G, the *residual graph* G_f is defined as follows.

- G_f has the same set of nodes as G (including s and t);
- for each e = (u, v) of G on which $f(e) < c_e$, e is in G_f and has capacity $c_e f(e)$; (such an edge is called a *forward edge* in G_f)
- for each e = (u, v) of G on which f(e) > 0, (v, u) is in G_f , and has capacity f(e). (such an edge is called a *backward edge* in G_f)

The capacities in G_f are sometimes called the *residual capacities*. Note that the residual capacities are all strictly positive.

Any (simple) s-t path in the residual graph G_f is called an *augmenting* path. In an augmenting path P in the residual graph G_f , the minimum residual capacity is called the *bottleneck*, denoted as bottleneck(P, f).

Any (simple) s-t path in the residual graph G_f is called an *augmenting* path. In an augmenting path P in the residual graph G_f , the minimum residual capacity is called the *bottleneck*, denoted as bottleneck(P, f).

Given a flow f in G, if there is an s-t path P in G_f , let b be bottleneck(P, f); we *augment* along P by doing the following for each edge e = (u, v) in P:

Any (simple) s-t path in the residual graph G_f is called an *augmenting* path. In an augmenting path P in the residual graph G_f , the minimum residual capacity is called the *bottleneck*, denoted as bottleneck(P, f).

Given a flow f in G, if there is an s-t path P in G_f , let b be bottleneck(P, f); we *augment* along P by doing the following for each edge e = (u, v) in P:

• if e is a forward edge, then we increase f(e) in G by b;

Any (simple) s-t path in the residual graph G_f is called an *augmenting* path. In an augmenting path P in the residual graph G_f , the minimum residual capacity is called the *bottleneck*, denoted as bottleneck(P, f).

Given a flow f in G, if there is an s-t path P in G_f , let b be bottleneck(P, f); we *augment* along P by doing the following for each edge e = (u, v) in P:

- if e is a forward edge, then we increase f(e) in G by b;
- if e = (u, v) is a backward edge in G_f , then edge (v, u) is in G with f((v, u)) > 0, we decrease f((v, u)) in G by b.

Any (simple) s-t path in the residual graph G_f is called an *augmenting* path. In an augmenting path P in the residual graph G_f , the minimum residual capacity is called the *bottleneck*, denoted as bottleneck(P, f).

Given a flow f in G, if there is an s-t path P in G_f , let b be bottleneck(P, f); we *augment* along P by doing the following for each edge e = (u, v) in P:

- if e is a forward edge, then we increase f(e) in G by b;
- if e = (u, v) is a backward edge in G_f , then edge (v, u) is in G with f((v, u)) > 0, we decrease f((v, u)) in G by b.

Proposition

The result of an augmentation, f', is a flow in G.

Ford-Fulkerson Algorithm

The Ford-Fulkerson algorithm:

• Initialize: $f(e) \leftarrow 0$ for all $e \in E$.

- Initialize: $f(e) \leftarrow 0$ for all $e \in E$.
- Iterate: construct G_f and search for an augmenting path. If no augmenting path can be found, terminate and return f(e)'s as the flow. Otherwise augment along the path and repeat.

- Initialize: $f(e) \leftarrow 0$ for all $e \in E$.
- Iterate: construct G_f and search for an augmenting path. If no augmenting path can be found, terminate and return f(e)'s as the flow. Otherwise augment along the path and repeat.

Running time: each round takes O(m) time, but how many rounds?

- Initialize: $f(e) \leftarrow 0$ for all $e \in E$.
- Iterate: construct G_f and search for an augmenting path. If no augmenting path can be found, terminate and return f(e)'s as the flow. Otherwise augment along the path and repeat.

Running time: each round takes O(m) time, but how many rounds? Suppose all capacities are integers. Let C be $\sum_{e \text{ out of } s} c_e$.

Claim

The Ford-Fulkerson algorithm terminates in at most C rounds.

- Initialize: $f(e) \leftarrow 0$ for all $e \in E$.

Running time: each round takes O(m) time, but how many rounds? Suppose all capacities are integers. Let C be $\sum_{e \text{ out of } s} c_e$.

Claim

The Ford-Fulkerson algorithm terminates in at most C rounds.

Running time O(Cm).

• By the proposition we showed, f(e)'s returned by Ford-Fulkerson is indeed a flow.

- By the proposition we showed, f(e)'s returned by Ford-Fulkerson is indeed a flow.
- It remains to show that it is a maximum flow.

- By the proposition we showed, f(e)'s returned by Ford-Fulkerson is indeed a flow.
- It remains to show that it is a maximum flow.
- A "primal-dual" argument: give many upper bounds on the value of any flow, and then show that the flow returned by Ford-Fulkerson is equal to one of these bounds.

- By the proposition we showed, f(e)'s returned by Ford-Fulkerson is indeed a flow.
- It remains to show that it is a maximum flow.
- A "primal-dual" argument: give many upper bounds on the value of any flow, and then show that the flow returned by Ford-Fulkerson is equal to one of these bounds.
- As a corollary, this will also show that maximum "primal" value (flow here) is equal to the minimum "dual" value (the best upper bound here).

 Given a graph G = (V, E), a cut is a partition of V into two sets A and B. That is, A ∩ B = Ø, A ∪ B = V.

Lemma

For any s-t cut (A, B) and any flow f, the value of f, |f|, is $f^{out}(A) - f^{in}(A)$.

The Max Flow Min Cut Theorem

Corollary

For any s-t cut (A, B) and any flow f, $|f| \leq c(A, B)$.

Corollary

For any s-t cut (A, B) and any flow f, $|f| \leq c(A, B)$.

Theorem (Max-Flow Min-Cut Theorem)

The following statements are equivalent:

- **1** *f* is a maximum flow on a flow network G with capacities c,
- 2 There is an s-t cut (A, B) with c(A, B) = |f|,
- O There exists no augmenting path in G_f.

Corollary

For any s-t cut (A, B) and any flow f, $|f| \leq c(A, B)$.

Theorem (Max-Flow Min-Cut Theorem)

The following statements are equivalent:

- **1** *f* is a maximum flow on a flow network G with capacities c,
- 2 There is an s-t cut (A, B) with c(A, B) = |f|,

3 There exists no augmenting path in G_f.

• This immediately implies the correctness of Ford-Fulkerson algorithm.

Corollary

For any s-t cut (A, B) and any flow f, $|f| \leq c(A, B)$.

Theorem (Max-Flow Min-Cut Theorem)

The following statements are equivalent:

- I f is a maximum flow on a flow network G with capacities c,
- 2 There is an s-t cut (A, B) with c(A, B) = |f|,

3 There exists no augmenting path in G_f.

- This immediately implies the correctness of Ford-Fulkerson algorithm.
- The s-t cut (A, B) with c(A, B) = |f| must have the minimum capacity among all s-t cuts, and hence is called a *minimum cut*.

• For flow networks with integer capacities, there is always an inter-valued maximum flow.

- For flow networks with integer capacities, there is always an inter-valued maximum flow.
 - This is an example where an algorithm has an implication that doesn't look algorithmic.

- For flow networks with integer capacities, there is always an inter-valued maximum flow.
 - This is an example where an algorithm has an implication that doesn't look algorithmic.
- For all flow networks (even whose capacities are not integral), a maximum flow exists.

- For flow networks with integer capacities, there is always an inter-valued maximum flow.
 - This is an example where an algorithm has an implication that doesn't look algorithmic.
- For all flow networks (even whose capacities are not integral), a maximum flow exists.
- Observation: given a maximum flow in a flow network, it takes additional O(m) time to find a minimum cut.
